## 8.5 Error Classes, Error Codes, and Error Handlers

Users may want to write a layered library on top of an existing MPI implementation, and this library may have its own set of error codes and classes. An example of such a library is an I/O library based on MPI, see Chapter 13 on page 373. For this purpose, functions are needed to:

- 1. add a new error class to the ones an MPI implementation already knows.
- 2. associate error codes with this error class, so that MPI\_ERROR\_CLASS works.
- 3. associate strings with these error codes, so that MPI\_ERROR\_STRING works.
- 4. invoke the error handler associated with a communicator, window, or object.

Several functions are provided to do this. They are all local. No functions are provided to free error classes or codes: it is not expected that an application will generate them in significant numbers.

```
MPI_ADD_ERROR_CLASS(errorclass)
```

OUT error class (integer)

int MPI\_Add\_error\_class(int \*errorclass)

MPI\_ADD\_ERROR\_CLASS(ERRORCLASS, IERROR)
INTEGER ERRORCLASS, IERROR

int MPI::Add\_error\_class()

Creates a new error class and returns the value for it.

Rationale. To avoid conflicts with existing error codes and classes, the value is set by the implementation and not by the user. (End of rationale.)

Advice to implementors. A high-quality implementation will return the value for a new errorclass in the same deterministic way on all processes. (End of advice to implementors.)

Advice to users. Since a call to MPI\_ADD\_ERROR\_CLASS is local, the same errorclass may not be returned on all processes that make this call. Thus, it is not safe to assume that registering a new error on a set of processes at the same time will yield the same errorclass on all of the processes. However, if an implementation returns the new errorclass in a deterministic way, and they are always generated in the same order on the same set of processes (for example, all processes), then the value will be the same. However, even if a deterministic algorithm is used, the value can vary across processes. This can happen, for example, if different but overlapping groups of processes make a series of calls. As a result of these issues, getting the "same" error on multiple processes may not cause the same value of error code to be generated. (End of advice to users.)
