```
void copyIntBuffer( int *pin, int *pout, int len )
{    int i;
    for (i=0; i<len; ++i) *pout++ = *pin++;
}
then a call to it in the following code fragment has aliased arguments.
int a[10];
copyIntBuffer( a, a+3, 7);</pre>
```

Although the C language allows this, such usage of MPI procedures is forbidden unless otherwise specified. Note that Fortran prohibits aliasing of arguments.

All MPI functions are first specified in the language-independent notation. Immediately below this, language dependent bindings follow:

- The ISO C version of the function.
- The Fortran version used with USE mpi_f08.
- The Fortran version of the same function used with USE mpi or INCLUDE 'mpif.h'.

An exception is Section 14.3 "The MPI Tool Information Interface", which only provides ISO C interfaces.

"Fortran" in this document refers to Fortran 90 and higher; see Section 2.6.

2.4 Semantic Terms

When discussing MPI procedures the following semantic terms are used.

nonblocking A procedure is nonblocking if the procedure may return before the operation completes, and before the user is allowed to reuse resources (such as buffers) specified in the call. A nonblocking request is started by the call that initiates it, e.g., MPI_ISEND. The word complete is used with respect to operations, requests, and communications. An operation completes when the user is allowed to reuse resources, and any output buffers have been updated; i.e., a call to MPI_TEST will return flag = true. A request is completed by a call to wait, which returns, or a test or get status call which returns flag = true. This completing call has two effects: the status is extracted from the request; in the case of test and wait, if the request was nonpersistent, it is freed, and becomes inactive if it was persistent. A communication completes when all participating operations complete.

blocking A procedure is blocking if return from the procedure indicates the user is allowed to reuse resources specified in the call.

local A procedure is local if completion of the procedure depends only on the local executing process.

non-local A procedure is non-local if completion of the operation may require the execution of some MPI procedure on another process. Such an operation may require communication occurring with another user process.
